Functions

Scope

- ▶ Namespace
 - ▶ Program stores names in separate namespaces
 - ▶ Location of name in code determines namespace

Scope

- ▶ Namespace

- ▶ Program stores names in separate namespaces
- ▶ Location of name in code determines namespace

- ▶ Functions

- ▶ If a variable is assigned inside a def, it is local to that function.
- ▶ If a variable is assigned outside all defs, it is global to the entire file.

Scope

- ▶ **LEGB Rule**
 - ▶ Local
 - ▶ Enclosing
 - ▶ Global
 - ▶ Built-in

Built-in (Python)

Names preassigned in the built-in names module: `open`, `range`, `SyntaxError`....

Global (module)

Names assigned at the top-level of a module file, or declared `global` in a `def` within the file.

Enclosing function locals

Names in the local scope of any and all enclosing functions (`def` or `lambda`), from inner to outer.

Local (function)

Names assigned in any way within a function (`def` or `lambda`), and not declared `global` in that function.

Pass by Reference vs Pass by Value

- ▶ Immutable arguments are “passed by value”
 - ▶ Objects such as integers and strings are passed by object reference instead of by copying
 - ▶ Since you can’t change immutable objects in place anyhow, the effect is much like making a copy.

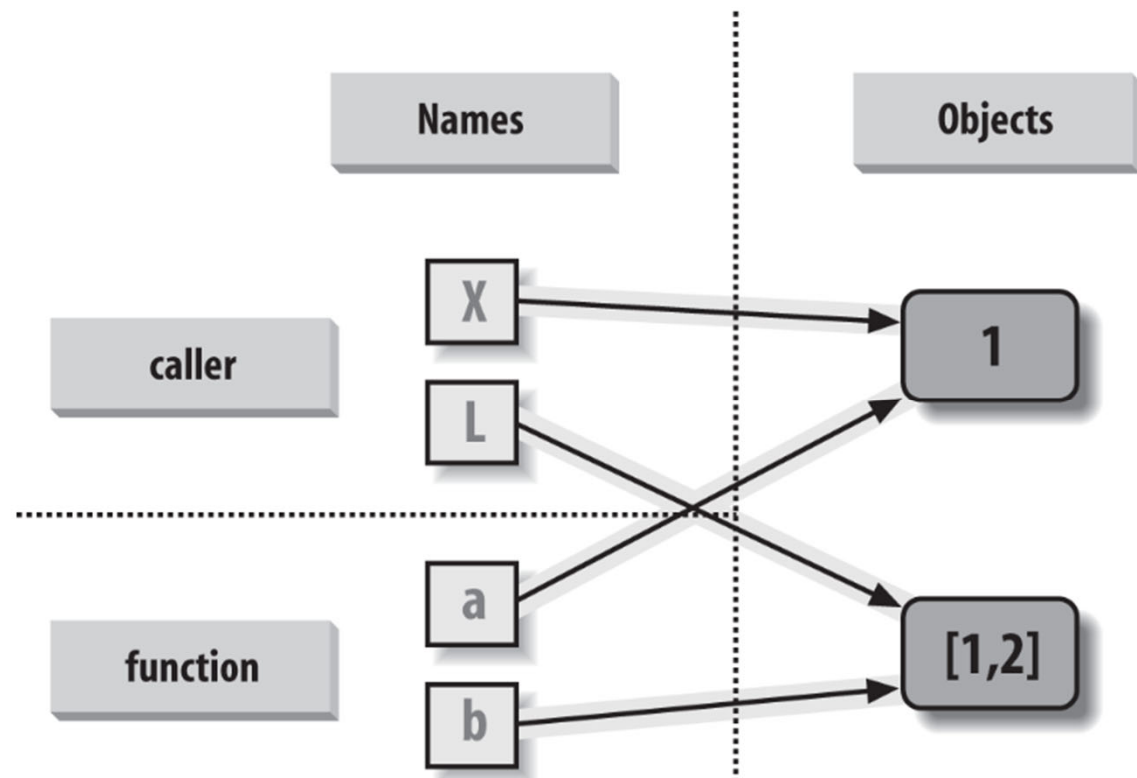

Pass by Reference vs Pass by Value

- ▶ Mutable arguments are “passed by reference”
 - ▶ Objects such as lists and dictionaries are passed by reference.
 - ▶ Mutable objects can be changed in place in the function

Pass by Reference vs Pass by Value

```
>>> def changer(a, b):  
    a = 2  
    b[0] = 'spam'
```

```
>>> X = 1  
>>> L = [1, 2]  
>>> changer(X, L)  
>>> X, L  
(1, ['spam', 2])
```

Positional Arguments vs Keyword Argument

Syntax	Location	Interpretation
<code>func(value)</code>	Caller	Normal argument: matched by position
<code>func(name=value)</code>	Caller	Keyword argument: matched by name

Unpacking Arguments

<code>func(*iterable)</code>	Caller	Pass all objects in <i>iterable</i> as individual positional arguments
------------------------------	--------	--

<code>func(**dict)</code>	Caller	Pass all key/value pairs in <i>dict</i> as individual keyword arguments
---------------------------	--------	---

Default Arguments

<code>def func(name)</code>	Function	Normal argument: matches any passed value by position or name
-----------------------------	----------	---

<code>def func(name=value)</code>	Function	Default argument value, if not passed in the call
-----------------------------------	----------	---

Variable Number of Inputs

<code>def func(*name)</code>	Function	Matches and collects remaining positional arguments in a tuple
------------------------------	----------	--

<code>def func(**name)</code>	Function	Matches and collects remaining keyword arguments in a dictionary
-------------------------------	----------	--

Recursion

```
>>> def mysum(L):  
    print(L)  
    if not L:  
        return 0  
    else:  
        return L[0] + mysum(L[1:])
```

```
>>> mysum([1, 2, 3, 4, 5])  
[1, 2, 3, 4, 5]  
[2, 3, 4, 5]  
[3, 4, 5]  
[4, 5]  
[5]  
[]  
15
```

Storing Values in Functions

- ▶ Closure

- ▶ Values of variables in local scope of function do not persist between calls. We can use inner functions to save values.

- ▶ Example (Currying functions)

```
def curry(first_argument, func):  
    def new_func(*args):  
        return func(first_argument, *args)  
  
    return new_func  
  
def adder(x, y):  
    return x + y  
  
curried_adder = curry(5, adder)  
curried_adder(4)
```

Classes and Objects

- ▶ Objects
 - ▶ Data (called state or *attributes*)
 - ▶ Functions (called behavior or *methods*)
- ▶ Classes
 - ▶ Each object is *instance* of class
 - ▶ Specifies attributes and methods

Encapsulation

```
class atom(superclass, ...):  
    class_attribute = value  
    ...  
    def method(self, ...):  
        self.instance_attribute = value  
    ...
```

- ▶ Class attribute
 - ▶ variable that is accessible by any instance of the class
 - ▶ All instances share the variable
- ▶ Instance attribute
 - ▶ only accessible by the instance that creates it
 - ▶ Like a local variable

Example (Instance attribute)

```
class atom:  
    def init(self, atomic_number, x, y, z):  
        self.atomic_number = atomic_number  
        self.position = (x, y, z)
```

```
x = atom()  
x.init(6, 0.0, 1.0, 2.0) # Carbon (C)  
y = atom()  
y.init(10, 4.0, 3.0, 5.0) # Neon (Ne)  
print(y.position)
```

Example (Class Attribute)

```
var = name()
```

```
var.class_attr = val
```

```
var.inst_attr = val
```

```
var.method(args...)
```

Inheritance

- ▶ Classes inherit common state and behavior from other classes
- ▶ Class that inherits from another class is called
 - ▶ subclass
 - ▶ Child class
 - ▶ Derived class
- ▶ Class that is inherited by other classes is called
 - ▶ superclass
 - ▶ Parent class
 - ▶ Base class

Example (Inheritance)

```
class Super:  
    def __init__(self, x):  
        ... default code ...
```

```
class Sub(Super):  
    def __init__(self, x, y):  
        Super.__init__(self, x)  
        ... custom code ...
```

Example (Inheritance)

Methods named with double underscores `__X__` are special hooks

Classes may override most built-in type operations

- `__init__` for object construction
- `__repr__` when printed or converted to a string
- `__add__` for `+` operator `X + Y`
- `__lt__`, `__gt__`, etc for comparisons `X < Y`, `X > Y`, etc.

Example (Inheritance)

In Python classes anything with two leading underscores is private

`__a_func` `__my_variable`

Internally, these are replaced with a name that includes the class name

`__name__a_func` `__name__my_variable`

Anything with one leading underscore is semi-private, and you should feel guilty accessing this data directly

`_b`

Take-Aways

- ▶ Divide and Conquer
 - ▶ Split large problem into small problems. Call function recursively on smaller problems.

Take-Aways

- ▶ Divide and Conquer
 - ▶ Split large problem into small problems. Call function recursively on smaller problems.
- ▶ Encapsulation and Inheritance
 - ▶ Classes includes attributes and methods. Compare to Abstraction and Decomposition for functions

Take-Aways

- ▶ Divide and Conquer
 - ▶ Split large problem into small problems. Call function recursively on smaller problems.
- ▶ Encapsulation and Inheritance
 - ▶ Classes includes attributes and methods. Compare to Abstraction and Decomposition for functions
- ▶ Debugging
 - ▶ Halt the execution of code to locate bugs
